

Stop Guessing, Start Measuring: A Systematic Prompt Enhancement Workflow for Production AI Systems

In many cases, teams develop prompts in a **relaxed manner**, similar to writing informal emails. This is a natural process, and not much thought is given to **structural elements**. This relaxed approach is appropriate for **exploratory development** or even **rapidly developing a prototype**.

But when one starts to use a feature that is built upon a Large Language Model **in front of actual users**, prompts become a **critical aspect**. If prompts are not designed well, it may result in failure, and the responses may not be consistent, important information may not be included, and the responses may not be reliable.

In addition to this, **debugging is unexpectedly complex** when a problem occurs. One is often required to find out if the problem is related to the **model, the input, or even the prompt**.

This post is going to go over the exact process we created to move prompts from 'probably good enough' to 'definitely good enough for production' with real criteria, real evaluation datasets, and real benchmarks across multiple models. Not magic. Just structured engineering applied to prompts.

Why Prompts Are More Than Just Instructions

When most people think of a prompt, they think of a simple request, like, "Summarize this document" or "Extract entities from this text." But in the real world, a prompt is so much more than that. It is the fundamental interface between your program and the model's behavior. A good prompt will create the persona for the model, the rules of engagement, the output format, and the unexpected.

The problem, with prompts is that they are not thoroughly tested. They are designed, implemented and then just of checked to see if they work. You make a change here and add a rule there. Then you just hope it works out okay. Sometimes it does work. Usually it doesn't. When it fails it just doesn't. You might not even notice.

What Actually Makes a Prompt "Good"?

A good prompt isn't just clear it's structured. Think of it like an API contract between you and the model. It should define:

- **A role or persona:** What context should the model operate from?
- **Instructions:** What exactly should it do?

- **Constraints:** What should it never do?
- **Output specification:** What format, structure, and length is expected?
- **Contextual guidance:** What background does the model need to act without making assumptions?
- **Examples:** What does good output look like?

When all of these are in place, the model has everything it needs to be consistent, reliable, and predictable across inputs and even across different model versions.

Prompt structure

1. Task context
2. Tone context
3. Background data, documents, and images
4. Detailed task description & rules
5. Examples
6. Conversation history
7. Immediate task description or request
8. Thinking step by step / take a deep breath
9. Output formatting
10. Prefilled response (if any)

User

You will be acting as an AI career coach named Joe created by the company AdAstra Careers. Your goal is to give career advice to users. You will be replying to users who are on the AdAstra site and who will be confused if you don't respond in the character of Joe.

You should maintain a friendly customer service tone.

Here is the career guidance document you should reference when answering the user: <guide>{{DOCUMENT}}</guide>

Here are some important rules for the interaction:

- Always stay in character, as Joe, an AI from AdAstra careers
- If you are unsure how to respond, say "Sorry, I didn't understand that. Could you repeat the question?"
- If someone asks something irrelevant, say, "Sorry, I am Joe and I give career advice. Do you have a career question today I can help you with?"

Here is an example of how to respond in a standard interaction:

```
<example>
User: Hi, how were you created and what do you do?
Joe: Hello! My name is Joe, and I was created by AdAstra Careers to give career advice. What can I help you with today?
</example>
```

Here is the conversation history (between the user and you) prior to the question. It could be empty if there is no history:

```
<history> {{HISTORY}} </history>
```

Here is the user's question: <question> {{QUESTION}} </question>

How do you respond to the user's question?

Think about your answer first before you respond.

Put your response in <response></response> tags.

Assistant (prefill)

```
<response>
```

The Real Cost of Poorly Structured Prompts in Production

Here's what we've seen happen with poor prompts in real-world deployments:

Outputs that look right but aren't : The model produces an answer that looks like it's in the correct format but has subtle errors because the specification wasn't clear.

Cross-model failures : The prompt works for GPT-4 but has inconsistent answers for Claude and OSS models. Nobody tested it across models before deployment.

Silent regressions : Changing one word to fix one problem causes three other problems that nobody noticed until someone complains.

The problem is always the same: nobody treated the prompt like something that needs to be tested and validated. We built this process to fix that.

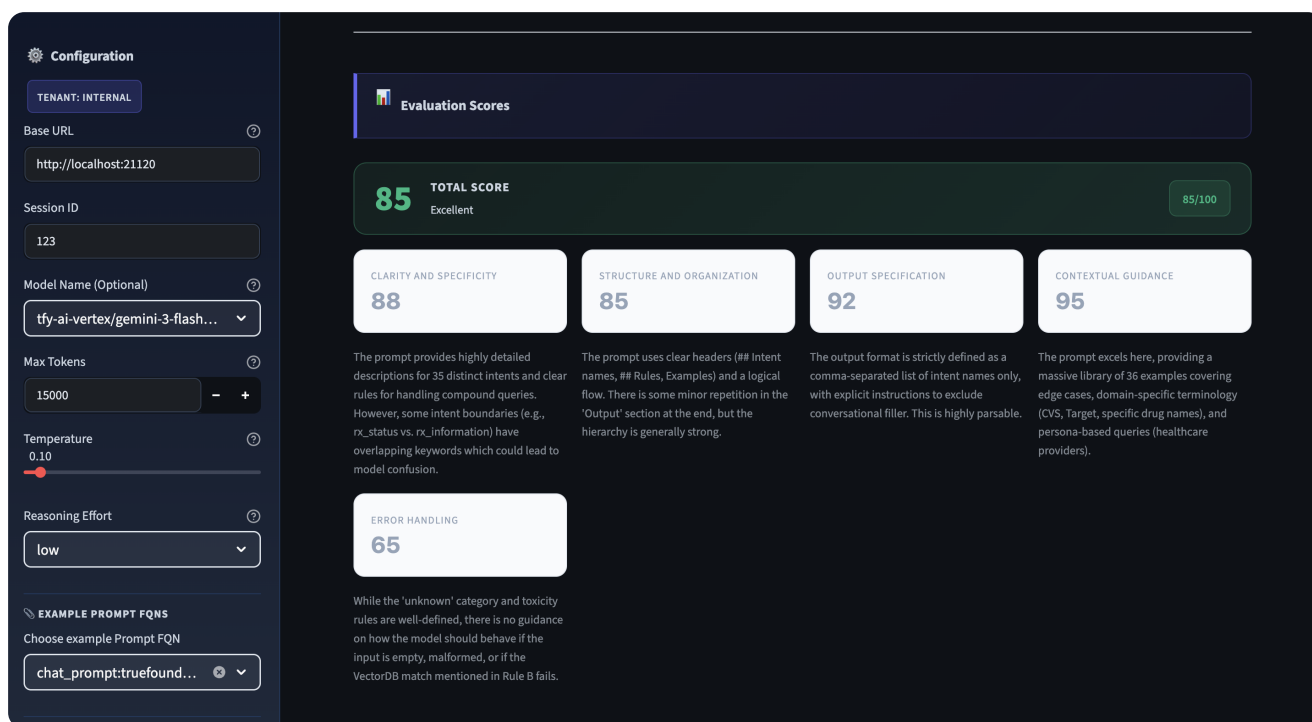

Our Prompt Enhancement Workflow : Step by Step

The workflow has five steps. Each one builds on the previous. Skip one and the results get unreliable fast. Here's how it works end to end.

Step 1 - Evaluating the Prompt

So, before making any changes, we want to know what's broken. We use a structured evaluation engine that runs on every prompt and scores it on five different dimensions and provides an overall quality score that ranges from 0 to 100.

We don't use subjective scoring. We have clear criteria for all dimensions. We have hard constraints. For example, if there is no output specification in the prompt, there is a maximum output specification score. The score can be high even if the instructions in the prompt are well-written. If the score is less than 75, it is not production-ready. If it is above 90, then it is solid on all dimensions.

Step 2 - Generating Recommendations Across 5 Criteria

This is the diagnostic engine of the workflow. Every prompt is scored 0–100 across five specific criteria. The overall score is the arithmetic mean of all five. Here's what each one measures and why it matters:

1. Clarity and Specificity

Are the instructions clear enough that two different models will understand them in exactly the same way? Vague instructions cause inconsistencies more than any other single factor. If you're unsure how a human might interpret your prompt, you're likely unsure how a model

will interpret it. If there's more than one way a human might interpret it, there's more than one way a model might interpret it correctly or incorrectly.

2. Structure and Organization

Does the prompt flow logically from context → instructions → constraints → output format? A disorganized prompt forces the model to figure out what matters and in what order. Good structure makes the model's job easier and your outputs more reliable.

3. Output Specification

Is the expected output format, structure, and length well-defined? If the output needs to be parsed by a subsequent parser, are there no ambiguities about what the output will look like? This checks the most common error condition: outputs that look right but can't be parsed.

4. Contextual Guidance

Does this prompt provide the model with sufficient context to perform without making assumptions? Models that must make assumptions will always make incorrect assumptions. Context such as domain terminology, boundary information, and context will eliminate this type of error completely.

5. Error Handling

Are edge cases covered? Does this prompt specify what to do in cases where the input is ambiguous, incomplete, or out of bounds? This is the most common one to miss and the one that causes the most production-related issues. Hallucinations, unexpected input formats, missing information – all this needs to be covered in this prompt.

Scoring scale: 90–100 is production-ready. 75–89 has gaps but is functional. 50–74 works but is unreliable. Below 50 means significant structural problems that need to be fixed before shipping.

Step 3 - Applying the Recommendations

We have the scores and explanations for each criterion. Next, we produce a concrete version of the improved prompt. The recommendations are not just abstract ideas. They correspond to actual changes to the prompt's structure. These changes include adding output specs that were missing, making unclear instructions more precise, dividing content and format-related issues, and making explicit the fallbacks for edge cases.

The main constraint that we impose is that of intent preservation. In other words, we are not re-writing the prompt. Rather, we are filling in the gaps that the evaluation highlighted while preserving the original intent and domain.

ck if it is covered under the customer's insurance policy.

12. drug_availability: User is asking for information about the availability of a particular drug at a CVS store, or check the inventory or drug availability.

- 13. rx_information: User is asking general inquires about a prescription, including details like the doctor's name who prescribed the drug or medicine, count of prescriptions, total medications user is taking, all the doctor's who prescribed drug for the user, dosage form, reason for taking the medication, and the expected price. Inventory or stock or drug availability is not part of rx_information.

+ 13. rx_information: User is asking general inquires about a prescription's static details, including details like the doctor's name who prescribed the drug or medicine, count of prescriptions, total medications user is taking, all the doctor's who prescribed drug for the user, dosage form, reason for taking the medication, and the expected price. This intent covers the 'what' and 'who' of the prescription. Inventory or stock or drug availability is not part of rx_information.

- 14. rx_status: User is asking about the status of their last prescription, estimated timelines for preparation and pick-up, managing their expectations for future pickups. User may also ask about picking up prescriptions for others. Keywords like order status, order, prescription, prescriptions, another prescription, different prescriptions etc

+ 14. rx_status: User is asking about the current progress or state of their last prescription, estimated timelines for preparation and pick-up, managing their expectations for future pickups. This intent covers the 'when' and 'where' in the fulfillment process. User may also ask about picking up prescriptions for others. Keywords like order status, order, prescription, prescriptions, another prescription, different prescriptions etc

15. rx_action_notes_status: User is asking queries where he seeks any actions are required by the customer or doctor, if there are any insurance issues, if the request has been denied.

Save Enhanced Prompt

> Debug: Last API Response

Step 4 - Testing on Evaluation Datasets

The enhanced prompt is not executed until it is first put to test. The test is carried out using a benchmark dataset that represents all possible scenarios and failures in relation to the application.

This process is necessary because making alterations to prompts that seem beneficial in theory might cause unintended problems in application. While making an output specification tighter might cause unintended problems in application because of its reliance on the model's flexibility in other situations, it might cause problems when combined with certain input types.

chat_prompt:truefoun... ✕ ▾

☐ Debug Session State

✓ Test Case 10 · Original: ⌚ 17.85s | Enhanced: ⌚ 1.38s

> Input

✓ Improved — The enhanced prompt improved the accuracy of the metric mapping and unit conversion, correctly identifying that 'response time' in a general request context refers to span duration (nanoseconds) rather than just model latency (milliseconds).

> Key Differences

▽ Original Output (tfy-ai-vertex/gemini-3-flash-preview) — overall 0.80

```
{ "filters": [ { "spanAttributeKey": "tfy.model.metric.latency_in_ms", "operator": "GREATER_THAN", "value": 3000 } ] }
```

▽ Enhanced Output (openai-main/gpt-4o) — overall 1.00

```
{ "filters": [ { "spanFieldName": "durationInNs", "operator": "GREATER_THAN", "value": 300000000 } ] }
```

▽ Metric Scores

Metric	Original	Enhanced	Δ
Completeness	1.000	1.000	+0.000
Accuracy	0.500	1.000	+0.500
Output Format Compliance	1.000	1.000	+0.000
Answer Relevance	1.000	1.000	+0.000
Prompt Instruction Adherence	0.500	1.000	+0.500
Overall	0.800	1.000	+0.200

Step 5 - Comparing Performance Across Metrics and Models

The final step is benchmarking. We compare the original and improved prompts across two dimensions:

- **Metrics:**

- General Quality: Clarity, Completeness, Accuracy, Conciseness, Professional Tone
- Guardrails / Classification: Output Format Compliance, Hallucination Avoidance
- Conversational: Answer Relevance, Prompt Instruction Adherence, Empathy & Tone

Overall score is the arithmetic mean of the selected metrics; **users can choose relevant metrics before evaluation.**

- **Models:** Gemini, GPT-5, Claude, and open-source models. While a prompt is optimized for one model, it can fail for another model, not because the prompt is incorrect, but because the models differ in how well they follow instructions, how much structure they can tolerate, and what they assume for unclear inputs.

The comparison view shows where the improvement is real, where it's model-specific, and where further iteration is needed before the prompt can be considered portable across providers.

Step 6 - Apply Suggestions & Refine

Subsequent to this, the LLM Judge scores both prompts, and improvement suggestions are provided in priority order, categorized as HIGH, MEDIUM, and LOW based on where the score delta between original and improved was weakest.

You select which suggestions to apply as recommendation, and the system sends them back through the same enhancement pipeline to produce a refined enhanced prompt. This feedback loop continuously improves the prompt by re-evaluating and refining it.

These are not general suggestions; they are test case-specific. The reason is that the Evaluator model is evaluating how well your original prompts and your enhanced prompts did in your test cases. These suggestions you're seeing are directly related to what was missing in your test case evaluation. If you were to add additional test cases to this evaluation, you might see different suggestions.

You can repeat this process as many times as needed. Each cycle uses the previously enhanced prompt as the new baseline, allowing improvements to compound. The final refined prompt can be downloaded directly from the UI and deployed using **True Foundry Gateway**.

The screenshot displays the True Foundry Gateway interface, divided into two main sections: Configuration and Suggestions.

Configuration Panel:

- TENANT:** INTERNAL
- Base URL:** http://localhost:21120
- Session ID:** 123
- Model Name (Optional):** tfy-ai-vertex/gemini-3-flash...
- Max Tokens:** 15000 (with minus and plus buttons)
- Temperature:** 0.10 (with a slider)
- Reasoning Effort:** low (with a dropdown menu)
- EXAMPLE PROMPT FQNS:** Choose example Prompt FQN: chat_prompt:truefoun... (with a dropdown menu)
- Debug Session State:** (with a toggle switch)

Suggestions Panel:

Suggestions

The enhanced prompt improved adherence to specific technical mappings (like nanosecond conversions and durationInNs), but suffered a significant regression in entity extraction. It frequently failed to identify span types (e.g., 'guardrail', 'model calls', 'tool calls') that the original prompt captured correctly, leading to lower completeness scores.

Select suggestions to apply to the enhanced prompt, then click Apply Selected.

- ☐ **HIGH**
Restore Span Type Extraction Logic
Add an explicit instruction: 'Always extract the span type (tfy.span_type) if the user query mentions specific entities like guardrails, model calls, tool calls, or agent executions.'
The enhanced prompt consistently missed these filters (Tests 5, 7, 9), which are critical for the API payload's accuracy and were handled better by the original prompt.
- ☐ **MEDIUM**
Enforce Pretty-Printed JSON Output
Add a formatting constraint: 'Output the final JSON in a multi-line, indented format (pretty-print) for better readability.'
The evaluation noted a consistent difference where the enhanced prompt switched to single-line JSON, whereas the original maintained a more readable multi-line structure.
- ☐ **MEDIUM**
Clarify Duration vs. Latency Mapping
Include a specific mapping rule: 'Map "response time" or "execution time" to the SpanFieldFilter "durationInNs". Map "model latency" specifically to the span attribute "tfy.model.metric.latency_in_ms".'
Test 10 showed the enhanced prompt is better at nanosecond conversion, but there is still ambiguity between general span duration and specific model latency attributes.
- ☐ **LOW**
Reinforce Entity-to-Span-Type Mapping
Provide a concise mapping table for common terms: 'tool calls' -> 'MCP', 'guardrail checks' -> 'Guardrail', 'model calls' -> 'Model'.
The model failed to map 'guardrail checks' and 'tool calls' to their respective span types in the enhanced version, leading to empty filter arrays.

Why the Same Prompt Behaves Differently Across Models

When we talk about engineering there is something that we often do not think about. The thing is that models like Gemini, GPT-5, Claude and LLaMA do not understand things in the way. This is because they were all trained in ways they learned from different sets of information and they were made to do things a little differently. So when we ask them something they might give us different answers. This is not because the question is bad. Because each model has its own way of doing things.

Some models are very good at following the rules and doing what we say. GPT-4 models for example might be very literal. LLama models might be more generative. Try to fill in the gaps. Claude models might be good at handling complicated questions. Other models might be better, at answering simple questions.

The only way to know how a prompt behaves across models is to test it. And the only way to make that testing systematic is to have an evaluation workflow like this one.

Managing Prompt Versions in Production with TrueFoundry Gateway

Once your prompt is evaluated, improved, and tested, you need a system to manage it over time versioning, environment-specific deployment, and the ability to roll back bad changes without redeploying your entire application.

This is where [TrueFoundry's AI Gateway](#) comes in. TrueFoundry provides a centralized prompt management system with built-in versioning every change to a prompt is tracked, and you can reference specific versions using human-readable aliases like `v1-prod` or `v2-staging`. The Gateway resolves the prompt version at runtime, which means prompt updates no longer require code redeployments.

Lessons Learned and Best Practices

As the workflow has been applied to a variety of prompts and projects, several key points have become apparent:

1. It is essential to always ensure that **diagnostic scores are obtained before editing**. The natural response to a problem is to start making changes as soon as the issue is recognized. This should be avoided. *Before making any changes, ensure diagnostics are captured*. The main problem is often located in an area that was not originally suspected.
2. **Keep output style separate from content**. Combining them creates ambiguity that subtly undermines consistency. The model should be made aware of the content and output styles separately.
3. **Do not skip error handling**. The additional effort only becomes apparent when unexpected inputs cause unintended behavior. *Specify error-handling paths to ensure cost efficiencies*.
4. **Treat prompts as code**. *Implement versioning and review before release* using the current toolset.
5. **Integrate cross-model testing early**. Discovering post-change that a prompt works for one model but not others is not ideal. *Make cross-model tests part of the standard workflow*.

Where This Goes Next : Prompt Engineering as a System

The goal we're working toward is making prompt quality as measurable and auditable as any other part of your software stack. That means automated regression testing for prompts when the underlying model version changes, prompt versioning integrated into your deployment pipeline, and evaluation dashboards that give visibility into prompt performance over time.

Prompt engineering is no longer considered a craft but a science. Organizations that treat it as such, and implement a formal process for evaluation, iteration, and testing, will be better positioned to build more reliable AI systems than those that do not. The process described in this workflow is an effort towards that end.
